Abstract

To address the hesitancy, inconsistency and uncertainty of decision makers cognitions, linguistic interval hesitant fuzzy sets (LIHFSs) are efficient tools. This paper focuses on studying the application of LIHFSs. To do this, two correlation coefficients of LIHFSs are defined, which needn’t consider the length of elements in LIHFSs or the arrangement of their possible interval values. To address the situation where the weights of elements in a set are different and correlative, two linguistic interval hesitant fuzzy Shapley weighted correlation coefficients are defined. Considering the situation where the weight information of features/attributes is partly known, programming models to determine the optimal fuzzy measures on them are constructed, respectively. After that, an approach to pattern recognition and multi-attribute decision making with linguistic interval hesitant fuzzy information is developed, respectively. Meanwhile, illustrative examples about medical diagnosis and selecting constructors for tunnel bidding are selected to verify the application of new approaches, and comparison with a previous method is offered.

Keywords: Decision making, pattern recognition, linguistic interval hesitant fuzzy set, correlation coefficient, distance measure.

1 Introduction

Decision making is one of the most common and important daily activities in human life. In the past half century, many researchers devoted themselves to studying the theory and application of decision making [6, 16, 17, 22, 38, 39, 60]. Bidding decision is an indispensable activity for bidder that plays an increasingly important role in the daily economic affairs. At present, there are five main methods for solving bidding problems under multi-risk factors, including the analytic hierarchy process (AHP) method, artificial neural network (ANN) method, fuzzy evaluation (FE) method, expert system (ES) method, and case-based reasoning (CBR) method. With the rapid development of human social-economic activities, it becomes more and more difficult to require decision makers (DMs) to provide exact attribute values. To address this issue, Zadeh’s fuzzy set theory is a good tool [57]. With the development of fuzzy decision-making theory, many types of fuzzy sets are presented, which can be classified into two types: One type is the quantitative fuzzy sets, such as [1, 12, 67]; the other type is the qualitative fuzzy sets, including [12, 23, 63, 65, 67, 68]. The emergence of fuzzy variables provides a new way to solve engineering bidding.

Many researchers have noted that quantitative variables cannot be used in some complex decision-making problems. To deal with this problem, linguistic variables [53] are good choices that own many good characteristics. However, the use of linguistic variables has drawbacks in modeling and calculating information. Considering this issue, several computing with word (CW) models have been proposed to broaden the application of decision making with linguistic variables in the literature [53, 17, 61, 63]. However, linguistic variables can only handle the exact qualitative information, which restricts the application. Xu [51] first noted this problem and introduced uncertain linguistic variables by extending the
discrete linguistic term set to the continuous linguistic term set. Taking the advantages of Atanassov’s intuitionistic fuzzy sets (IFSs) [1], interval-valued intuitionistic fuzzy sets (IVIFSs) [2] and linguistic variables [55], Wang and Li [13] gave intuitionistic linguistic sets (ILSs), Liu and Jin [21] proposed intuitionistic uncertain linguistic sets (IULSs), and Liu [20] introduced interval-valued intuitionistic uncertain linguistic sets (IVIULSs). As Torra [32] noted when a DM makes a judgment, several possible values may exist. Thus, Torra [32] introduced the concept of hesitant fuzzy sets (HFSs), which apply several possible values in $[0, 1]$ to denote a judgement. After the original work of Torra [32], Chen et al. [4] further introduced interval-valued hesitant fuzzy sets (IVHFSs) that use several intervals in $[0, 1]$ to express a judgment. As the above mentioned limitation, HFSs and IVHFSs can only denote the quantitative opinions of the DMs. Thus, Rodriguez et al. [33] proposed hesitant fuzzy linguistic term sets (HFLTSs), which use several linguistic variables to denote the qualitative hesitancy of DMs’ recognitions. Following the original work of Rodriguez et al. [33], several methods for decision making with HFLTSs are developed [15, 17, 18, 38]. To express the quantitative and qualitative hesitancy of DMs, several types of hybrid hesitant fuzzy sets are proposed in the literature [13, 24, 27, 21, 61, 13].

Correlation coefficient [1, 10] is one of the most important indices that has been received considerable attention in many fields, such as digital image processing [17, 56], clustering analysis [8, 66], and decision making [18, 52]. To address fuzzy decision-making information, Dumitrescu [9] extended correlation to fuzzy situations and proposed the concept of fuzzy correlation, Yu [52] introduced fuzzy correlation and correlation coefficient to measure the interrelation of sets. Chiang and Lin [2] defined fuzzy correlation coefficients by adopting the idea of conventional statistics, and Hong [13] adopted the weakest t-norm (TW)-based fuzzy arithmetic operations to research fuzzy correlation coefficient. Furthermore, several extended types of fuzzy correlation coefficients are proposed in the literature [11, 7, 10, 11, 12, 22, 51, 52, 51]. Note that Xu and Xia’s hesitant fuzzy correlation coefficients and Chen et al.’s interval-valued hesitant fuzzy correlation coefficients require the considered HFSs or IVHFSs to have the same length. In contrast to these correlation coefficients, Meng et al. [23, 24] further presented several new correlation coefficients of HFSs and IVHFSs that neither consider the length of (IVHFSs) HFSs nor the arrangement of the possible (interval) values.

Considering there is no research on correlation coefficient of LIHFSs, which restricts the application of LIHFSs. Following the works of Meng at al. [23, 21], this paper studies the correlation coefficients of LIHFSs and defines linguistic interval hesitant fuzzy correlation coefficients, which needn’t consider the length of the compared LIHFSs or the arrangement of the possible interval values. The remainder of this paper is organized as follows:

In Section 2, several basic concepts related to IVHFSs, LIHFSs, fuzzy measures, 2-additive measures and the Shapley coefficient, and the Shapley weighted correlation coefficients. In Section 4, a programming model for determining the optimal 2-additive measure on the attribute set are constructed. Then, an approach to decision making with LIHFSs is provided. Meanwhile, an example about selecting constructors for tunnel bidding is offered to verify the application of the new method. The conclusions are made in the last.

## 2 Basic concepts

To cope with the situation where several possible values exist for a judgment, Torra [32] introduced hesitant fuzzy sets (HFSs) that use several values in $[0, 1]$ to denote the possible membership degrees. Later, Chen et al. [4] extended HFSs to interval-valued hesitant fuzzy sets (IVHFSs) and gave the following definition:

**Definition 2.1.** [4] Let $X = \{x_1, x_2, \ldots, x_n\}$ be a finite set. An IVHFS $\tilde{A}$ on $X$ is in terms of a function that when applied to $X$ returns to a subset of $D[0, 1]$, denoted by $\tilde{A} = \{< x_i, \tilde{h}_A(x_i) > | x_i \in X \}$, where $\tilde{h}_A(x_i)$ is a set of all possible interval membership degrees of the element $x_i \in X$ to $\tilde{A}$ with $D[0, 1]$ being the set of all closed subintervals in $[0, 1]$. For convenience, Chen et al. [9] called $\tilde{h}_A(x_i)$ an interval-valued hesitant fuzzy element.

To express the hesitancy and uncertainty of DMs’ qualitative and quantitative cognitions, Meng et al. [31] introduced the concept of linguistic interval hesitant fuzzy sets (LIHFSs) as follows:

**Definition 2.2.** [31] Let $X = \{x_1, x_2, \ldots, x_n\}$ be a finite set, and let $S = \{s_1, s_2, \ldots, s_{2t+1}\}$ be the predefined linguistic term set. A LIHFS on $X$ is a set that when applied to the linguistic terms of $S$ it returns to a subset of $S$ with several intervals in $[0, 1]$, denoted by LIH = $\{(s_{\theta(i)}, \tilde{h}(s_{\theta(i)})) | s_{\theta(i)} \in S\}$, where $\tilde{h}(s_{\theta(i)}) = \{\tilde{r}_{i1}, \tilde{r}_{i2}, \ldots, \tilde{r}_{im}\}$ is a set with $m$ intervals in $[0, 1]$ denoting the possible interval membership degrees of the linguistic term $s_{\theta(i)}$ to LIH.
For example, to evaluate the quality of a mobile phone for the predefined linguistic term set $S = \{s_1: \textit{poor}, s_2: \textit{slightly poor}, s_3: \textit{average}, s_4: \textit{slightly good}, s_5: \textit{good}\}$, a DM may hesitate to give the interval $[0.2, 0.3]$ or $[0.4, 0.6]$ for slightly poor, the interval $[0.2, 0.5], [0.6, 0.7]$ or $[0.8, 0.9]$ for slightly good, and the interval $[0.3, 0.4]$ for good. To deal with this situation, LIHFSs are effective tools, and the above evaluation for the quality of a mobile phone can be expressed by LIH (quality) $=(s_2, [0.2, 0.3], [0.4, 0.6]), (s_4, [0.2, 0.5], [0.6, 0.7], [0.8, 0.9]), (s_5, [0.3, 0.4])$.

For any LIHFS LIH $= \{ (s_{\theta(i)}), h(s_{\theta(i)}) \} | s_{\theta(i)} \in S\}$, when $h(s_{\theta(i)}) = \{1,1\}$ for each linguistic variable $s_{\theta(i)}$, then it degenerates to a hesitant fuzzy linguistic term set (HFLTS) \cite{39}. Furthermore, when each interval preferred degree in $h(s_{\theta(i)})$ reduces to a real number for every linguistic variable $s_{\theta(i)}$, then it reduces to a linguistic hesitant fuzzy set (LHFS) \cite{30}.

**Definition 2.3.** \cite{31} Let LIH$_1$ be a LIHFS. Then, the complement of LIH$_1$ is denoted as:

$$(LIH_1)^c = \left\{ s_{2t+1-\theta(i)}, \bigcup_{\tau_i \in \Pi(s_{\theta(i)})} [1-r_i^+, 1-r_i^-] \mid s_{\theta(i)} \in S \right\}$$

(1)

In practical decision-making problems, the independence between the weights of elements in a set is usually violated. To solve this issue, fuzzy measures \cite{31} are efficient tools.

**Definition 2.4.** \cite{31} A fuzzy measure $\mu$ on the finite set $N = \{1, 2, \ldots, n\}$ is a set function $\mu: P(N) \rightarrow [0, 1]$ satisfying

(i) $\mu(\emptyset) = 0, \mu(N) = 1$;

(ii) If $A, B \in P(N)$ and $A \subseteq B$, then $\mu(A) \leq \mu(B)$, where $P(N)$ is the power set of $N$.

From the definition of fuzzy measures, one can find that they are defined on the power set, which cannot be used as the weights of elements directly. To overcome the issue, researchers adopted the following Shapley function \cite{31}:

$$\varphi_i(\mu, N) = \sum_{s \subseteq N \backslash i} \frac{(n-s-1)!s!}{n!} (\mu(S \cup i) - \mu(S)) \quad \forall i \in N$$

(2)

where $\mu$ is a fuzzy measure on $N = \{1, 2, \ldots, n\}$, $s$ and $n$ denote the cardinalities of $S$ and $N$, respectively.

Formula (2) shows that the Shapley value is an expect value, which globally reflects the interactions among the weights of elements. Definition 2.4 shows that $\varphi_i(\mu, N) \geq 0$ for any $i \in N$ and $\sum_{i=1}^{n} \varphi_i(\mu, N) = 1$. Thus, $\{\varphi_i(\mu, N)\}_{i \in N}$ is a weight vector. When there is no interaction, the Shapley value reduces an additive weight, where $\varphi_i(\mu, N) = \mu(i) = \omega_i \geq 0$ for any $i \in N$ and $\sum_{i=1}^{n} \omega_i = 1$. Because fuzzy measures are defined on the power set, 2-additive measures \cite{31} are good choices to reduce the complexity of solving fuzzy measures.

**Definition 2.5.** \cite{31} The fuzzy measure $\mu$ on $N = \{1, 2, \ldots, n\}$ is called a 2-additive measure, if, for any $S \subseteq N$ with $s \geq 2$, the following is true:

$$\mu(S) = \sum_{\{i,j\} \subseteq S} \mu(i,j) - (s-2) \sum_{i \in S} \mu(i)$$

(3)

where $s$ is the cardinality of $S$.

**Theorem 2.6.** \cite{31} $\mu$ is a 2-additive measure on $N = \{1, 2, \ldots, n\}$ if and only if, for all $i, j \in N$, the following conditions hold:

(i) $\mu(i) \geq 0 \ \forall i \in N$;

(ii) $\sum_{\{i,j\} \subseteq S} \mu(i,j) - (n-2) \sum_{i \in N} \mu(i) = 1$;

(iii) $\sum_{i \leq S \cup j} (\mu(i,j) - \mu(i)) \geq (s-2) \mu(j) \ \forall j \in S \subseteq N$ and $s \geq 2$,

where $s$ and $n$ denote the cardinalities of $S$ and $N$, respectively.
With respect to the 2-additive measure $\mu$, the Shapley function can be expressed as follows [26]:

$$\varphi_i(\mu, N) = \frac{3}{2} - n \mu(i) + \frac{1}{2} \sum_{j \in N \setminus i} (\mu(i, j) - \mu(j))$$

(4)

where $N = \{1, 2, \ldots, n\}$.

3 Correlation coefficients of LIHFSs

Correlation coefficients are effective tools that have been applied in many fields. In this section, we research correlation coefficients of LIHFSs, which neither consider the length of the compared LIHFSs nor the arrangement of the possible interval membership degrees. To do this, a distance measure for LIHFSs is defined. In contrast to Meng et al.’s coefficients of LIHFSs, which neither consider the length of the compared LIHFSs nor the arrangement of the possible interval membership degrees. To do this, a distance measure for LIHFSs is defined. In contrast to Meng et al.’s distance measure [31], we derive $ED(LIH_1, LIH_2) = 0$, by which we conclude that these two sets are equal. However, one can obviously see that these two sets are different. To overcome this disadvantage, we define a new distance measure for LIHFSs.

3.1 A distance measure

Let $LIH_1 = \{(s_{\theta(i)}, \tilde{h}(s_{\theta(i)})) | s_{\theta(i)} \in S\}$ and $LIH_2 = \{(s_{\theta(j)}, \tilde{h}(s_{\theta(j)})) | s_{\theta(j)} \in S\}$ be any two LIHFSs for the predefined linguistic term set $S = \{s_1, s_2, \ldots, s_{2t+1}\}$.

The distance between intervals $\bar{r}_{ik} \in \tilde{h}(s_{\theta(i)})$ and $\bar{r}_{jp} \in \tilde{h}(s_{\theta(j)})$ is defined as follows [35]:

$$d(\bar{r}_{ik}, \bar{r}_{jp}) = \frac{1}{2} \left( |r_{ik}^- - r_{jp}^-| + |r_{ik}^+ - r_{jp}^+| \right)$$

(5)

Using formula (5), the distance between $\bar{r}_{ik} \in \tilde{h}(s_{\theta(i)})$ and $\bar{h}(s_{\theta(j)})$ is defined as follows [52]:

$$d(\bar{r}_{ik}, \tilde{h}(s_{\theta(j)})) = \min_{\bar{r}_{jp} \in \tilde{h}(s_{\theta(j)})} \left( \frac{1}{2} \left( |r_{ik}^- - r_{jp}^-| + |r_{ik}^+ - r_{jp}^+| \right) \right)$$

(6)

Furthermore, the distance from $\tilde{h}(s_{\theta(i)})$ to $\tilde{h}(s_{\theta(j)})$ is defined as follows:

$$d(\tilde{h}(s_{\theta(i)}), \tilde{h}(s_{\theta(j)})) = \frac{1}{m} \sum_{k=1}^{m} \min_{\bar{r}_{jp} \in \tilde{h}(s_{\theta(j)})} \left( \frac{1}{2} \left( |r_{ik}^- - r_{jp}^-| + |r_{ik}^+ - r_{jp}^+| \right) \right)$$

(7)

Let $S = \{s_1, s_2, \ldots, s_{2t+1}\}$ be the predefined linguistic term set, and let $s_{\theta(i)}, s_{\theta(j)} \in S$. Then, the distance measure between $s_{\theta(i)}$ and $s_{\theta(j)}$ is defined as follows [35]:

$$d(s_{\theta(i)}, s_{\theta(j)}) = \frac{1}{m} |\theta(i) - \theta(j)|$$

(8)

Based on distance measures on interval possible membership degrees and on linguistic variables, the distance measure from an element in a LIHFS to another LIHFS is defined as follows:

**Definition 3.1.** Let $LIH_1$ and $LIH_2$ be any two LIHFSs for the predefined linguistic term set $S = \{s_1, s_2, \ldots, s_{2t+1}\}$. The distance measure from $(s_{\theta(i)}, \tilde{h}(s_{\theta(i)})) \in LIH_1$ to $LIH_2$ is defined as follows:

$$d((s_{\theta(i)}, \tilde{h}(s_{\theta(i)})), LIH_2) = \min_{(s_{\theta(j)}, \tilde{h}(s_{\theta(j)})) \in LIH_2} \left( \frac{1}{m} |\theta(i) - \theta(j)| \vee \left( \frac{1}{m} \sum_{k=1}^{m} \min_{\bar{r}_{jp} \in \tilde{h}(s_{\theta(j)})} \left( \frac{1}{2} \left( |r_{ik}^- - r_{jp}^-| + |r_{ik}^+ - r_{jp}^+| \right) \right) \right) \right)$$

(9)
\[
\begin{aligned}
&\left(\frac{1}{n} |\theta(i) - \theta(j)| \right) \land \left( \frac{1}{m} \sum_{k=1}^{m} \min_{r_k \in \mathcal{R}(s(i))} \left| r_i^k - r_j^k \right| + \left| r_i^k - r_j^k \right| \right) \\
&= \left( \frac{1}{n} \min_{(s(i), \bar{r}(s(i))) \in LIH_2} \left\{ \frac{1}{2} \left( \frac{1}{n} |\theta(i) - \theta(j)| + \frac{1}{m} \sum_{p=1}^{m} \min_{r_p \in \mathcal{R}(s(i))} \left| r_i^p - r_j^p \right| + \left| r_i^p - r_j^p \right| \right) \right\} \\
&\quad + \left( \frac{1}{m} \sum_{k=1}^{m} \min_{r_k \in \mathcal{R}(s(i))} \left| r_i^k - r_j^k \right| + \left| r_i^k - r_j^k \right| \right)
\end{aligned}
\]

Similarly, the distance measure from \((s(j), \bar{h}(s(j))) \in LIH_2\) to LIH_1 is defined as follows:

\[
\begin{aligned}
d \left((s(j), \bar{h}(s(j))), LIH_1\right) &= \min_{(s(i), \bar{r}(s(i))) \in LIH_1} \left\{ \frac{1}{2} \left( \frac{1}{n} |\theta(j) - \theta(i)| + \frac{1}{m} \sum_{p=1}^{m} \min_{r_p \in \mathcal{R}(s(i))} \left| r_i^p - r_j^p \right| + \left| r_i^p - r_j^p \right| \right) \right\}
\end{aligned}
\]

Following Definition 3.1, the distance measure from one LIHFS to the other is defined as follows:

**Definition 3.2.** Let LIH_1 and LIH_2 be any two LIHFSs for the predefined linguistic term set \(S = \{s_1, s_2, \ldots, s_{2t+1}\}\). The distance measure from LIH_1 to LIH_2 is defined as follows:

\[
\begin{aligned}
d \left(LIH_1, LIH_2\right) &= \frac{1}{|LIH_1|} \sum_{i=1}^{|LIH_1|} d \left((s(i), \bar{h}(s(i))), LIH_2\right)
\end{aligned}
\]

and the distance measure from LIH_2 to LIH_1 is defined as follows:

\[
\begin{aligned}
d \left(LIH_2, LIH_1\right) &= \frac{1}{|LIH_2|} \sum_{j=1}^{|LIH_2|} d \left((s(j), \bar{h}(s(j))), LIH_1\right)
\end{aligned}
\]

where \((s(i), \bar{h}(s(i))) \in LIH_1, (s(j), \bar{h}(s(j))) \in LIH_2, |LIH_1|\) and \(|LIH_2|\) denote the numbers of terms in the LIHFSs LIH_1 and LIH_2, respectively.

**Example 3.3.** Let \(S = \{s_1, s_2, s_3, s_4, s_5\}\) be the predefined linguistic term set, and let LIH_1 = \{(s_2, [0.2, 0.3], [0.5, 0.6]), (s_3, [0.1, [0.2, [0.4, 0.5]]) and LIH_2 = \{(s_2, [0.3, 0.4]), (s_3, [0.5, 0.6], [0.7, 0.8]), (s_4, [0.2, 0.4])\}.

Following formulae (9), (10), (11) and (12), we have

\[d \left(LIH_1, LIH_2\right) = 0.0938, d \left(LIH_2, LIH_1\right) = 0.1167.\]

Example 3.3 shows that \(d \left(LIH_1, LIH_2\right) \neq d \left(LIH_2, LIH_1\right)\), namely, distance measures listed in Definition 3.2 dissatisfy symmetry. To address this problem, we further introduce the following distance measure between LIHFSs:

**Definition 3.4.** Let LIH_1 and LIH_2 be any two LIHFSs for the predefined linguistic term set \(S = \{s_1, s_2, \ldots, s_{2t+1}\}\). The distance measure between LIH_1 and LIH_2 is defined as:

\[
\begin{aligned}
d \left(LIH_1, LIH_2\right) &= \frac{d \left(LIH_1, LIH_2\right) + d \left(LIH_2, LIH_1\right)}{2}
\end{aligned}
\]

where \(d \left(LIH_1, LIH_2\right)\) and \(d \left(LIH_2, LIH_1\right)\) as shown in Definition 3.2.

In Example 3.3, we have \(d \left(LIH_1, LIH_2\right) = 0.105\) using formula (13).

To show the rationality of the distance measure shown in Definition 3.4, we consider the following property:

**Property 3.5.** Let LIH_1 and LIH_2 be any two LIHFSs for the predefined linguistic term set \(S = \{s_1, s_2, \ldots, s_{2t+1}\}\). Then,

(i) \(d \left(LIH_1, LIH_2\right) = 0\) if and only if LIH_1 = LIH_2, namely, if and only if \((s(i), \bar{h}(s(i))) \in LIH_1\) and \((s(j), \bar{h}(s(j))) \in LIH_2\) for all \(i = 1, \ldots, |LIH_1|\) and all \(j = 1, \ldots, |LIH_2|\);

(ii) \(0 \leq d \left(LIH_1, LIH_2\right) \leq 1\);

(iii) \(d \left(LIH_1, LIH_2\right) = d \left(LIH_2, LIH_1\right)\).
Proof. For (i): When \( d(LIH_1, LIH_2) = 0 \), we have \( d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_2) \) = 0 for any \((s_{\theta(i)}, \bar{h}(s_{\theta(i)})) \in LIH_1 \) and \( d((s_{\theta(j)}, \bar{h}(s_{\theta(j)})), LIH_1) \) = 0 for any \((s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_2 \). Thus,

\[
\min_{(s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_2} \frac{1}{2} \left( \frac{1}{m} \sum_{k=1}^{m} \min_{\bar{r}_{ik} \in \bar{h}(s_{\theta(j)})} \left| r_{ik}^+ - r_{ik}^- \right| \right) = 0
\] (14)

and

\[
\min_{(s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_1} \frac{1}{2} \left( \frac{1}{n} \sum_{p=1}^{n} \min_{\bar{r}_{pj} \in \bar{h}(s_{\theta(j)})} \left| r_{pj}^+ - r_{pj}^- \right| \right) = 0
\] (15)

Following formula (14), we get \( |\theta(i) - \theta(j)| = 0 \) and \( |r_{ik}^- - r_{jk}^-| = |r_{ik}^+ - r_{jk}^+| = 0 \) for some \((s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_2 \) with \( \bar{r}_{ik} \in \bar{h}(s_{\theta(i)}) \), \( k = 1, 2, ..., m \). Thus, \((s_{\theta(j)}, \bar{h}(s_{\theta(j)})) = (s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_2 \).

Similarly, we obtain \((s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_1 \) based on formula (15).

On the basis of the above discussions, we have \( d(LIH_1, LIH_2) = 0 \). On the other hand, from \((s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_1 \) and \((s_{\theta(i)}, \bar{h}(s_{\theta(i)})) \in LIH_2 \) for all \( i = 1, ..., |L IH_1| \) and all \( j = 1, ..., |L IH_2| \), one can easily obtain that \( d(LIH_1, LIH_2) = 0 \) based on formula (13).

The conditions (ii) and (iii) are obvious. \( \square \)

**Property 3.6.** Let \( LIH_1, LIH_2 \) and \( LIH_3 \) be any three LHFSs for the predefined linguistic term set \( S = \{s_1, s_2, ..., s_{2l+1}\} \). If we have

\[
d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_3) \leq d((s_{\theta(j)}, \bar{h}(s_{\theta(j)})), LIH_3) \quad \text{and} \quad d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_1) \leq d((s_{\theta(j)}, \bar{h}(s_{\theta(j)})), LIH_2)
\]

for any \((s_{\theta(i)}, \bar{h}(s_{\theta(i)})) \in LIH_1 \), any \((s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_2 \) and any \((s_{\theta(l)}, \bar{h}(s_{\theta(l)})) \in LIH_3 \), then \( d(LIH_1, LIH_3) \leq d(LIH_2, LIH_3) \).

**Proof.** From Definitions 3.2 and 3.4, we obtain

\[
d(LIH_1, LIH_3) = \frac{1}{2} \left( \frac{1}{|L IH_1|} \sum_{i=1}^{|L IH_1|} d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_3) + \frac{1}{|L IH_3|} \sum_{i=1}^{|L IH_3|} d((s_{\theta(l)}, \bar{h}(s_{\theta(l)})), LIH_1) \right)
\]

and

\[
d(LIH_2, LIH_3) = \frac{1}{2} \left( \frac{1}{|L IH_2|} \sum_{i=1}^{|L IH_2|} d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_3) + \frac{1}{|L IH_3|} \sum_{i=1}^{|L IH_3|} d((s_{\theta(l)}, \bar{h}(s_{\theta(l)})), LIH_2) \right)
\]

Because \( d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_3) \leq d((s_{\theta(j)}, \bar{h}(s_{\theta(j)})), LIH_3) \) for any \((s_{\theta(i)}, \bar{h}(s_{\theta(i)})) \in LIH_1 \), and any \((s_{\theta(j)}, \bar{h}(s_{\theta(j)})) \in LIH_2 \), we derive

\[
\frac{1}{|L IH_1|} \sum_{i=1}^{|L IH_1|} d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_3) \leq \frac{1}{|L IH_2|} \sum_{i=1}^{|L IH_2|} d((s_{\theta(i)}, \bar{h}(s_{\theta(i)})), LIH_3)
\]

Similarly, we have

\[
\frac{1}{|L IH_3|} \sum_{i=1}^{|L IH_3|} d((s_{\theta(l)}, \bar{h}(s_{\theta(l)})), LIH_1) \leq \frac{1}{|L IH_3|} \sum_{i=1}^{|L IH_3|} d((s_{\theta(l)}, \bar{h}(s_{\theta(l)})), LIH_2)
\]

from \( d((s_{\theta(l)}, \bar{h}(s_{\theta(l)})), LIH_1) \leq d((s_{\theta(l)}, \bar{h}(s_{\theta(l)})), LIH_2) \) for any \((s_{\theta(l)}, \bar{h}(s_{\theta(l)})) \in LIH_3 \). Thus, \( d(LIH_1, LIH_3) \leq d(LIH_2, LIH_3) \). \( \square \)
3.2 Correlation of LIHFSs

This subsection focuses on the correlation of LIHFSs. To do this, we first introduce the following notations:

Let $LIH_1$ and $LIH_2$ be any two LIHFSs for the predefined linguistic term set $S = \{s_1, s_2, ..., s_{2t+1}\}$. If

$$d((s_{\theta(i)}, \tilde{h}(s_{\theta(i)})), (s_{\theta(j)}, \tilde{h}(s_{\theta(j)}))) = d((s_{\theta(i)}, \tilde{h}(s_{\theta(i)})), LIH_2)$$

(16)

for $(s_{\theta(i)}, \tilde{h}(s_{\theta(i)})) \in LIH_1$ and $(s_{\theta(j)}, \tilde{h}(s_{\theta(j)})) \in LIH_2$. Then, we denote $(s_{\theta(i)}, \tilde{h}(s_{\theta(i)}))$ as $(s_{\theta(i)}, \tilde{h}^i(s_{\theta(i)}))$.

Formula (9) shows that $(s_{\theta(j)}, \tilde{h}(s_{\theta(j)})) \in LIH_2$ is the element with the smallest distance to $(s_{\theta(i)}, \tilde{h}(s_{\theta(i)})) \in LIH_1$. To denote this relationship, we give the above notation.

Similarly, with respect to $(s_{\theta(i)}, \tilde{h}(s_{\theta(i)}))$ and $(s_{\theta(j)}, \tilde{h}^i(s_{\theta(j)}))$, if we have

$$d(\tilde{r}_i, \tilde{r}_j) = d(\tilde{r}_i, \tilde{h}(s_{\theta(j)}))$$

(17)

with $\tilde{r}_j \in \tilde{h}(s_{\theta(i)})$, then $\tilde{r}_j$ is denoted by $\tilde{r}_{i\theta}$, where $\tilde{r}_i \in \tilde{h}(s_{\theta(i)})$, $k = 1, 2, ..., m$.

Using these notations, the correlation of LIHFSs is defined as follows:

**Definition 3.7.** Let $LIH_1 = (s_{\theta(i)}, \tilde{h}(s_{\theta(i)}))$ and $LIH_2 = (s_{\theta(j)}, \tilde{h}(s_{\theta(j)}))$ be any two LIHFSs for the predefined linguistic term set $S = \{s_1, s_2, ..., s_{2t+1}\}$. Then, their correlation is defined as:

$$C(LIH_1, LIH_2) = \sum_{(s_{\theta(i)}, \tilde{h}(s_{\theta(i)})) \in LIH_1} \frac{1}{(2t+1)^2 \#\tilde{h}(s_{\theta(i)})} \sum_{\tilde{r}_{ik} \in \tilde{h}(s_{\theta(i)}); \tilde{r}_{ik} \in \tilde{h}^i(s_{\theta(i)})} \left( \theta(i)r^{-}_{ik}\theta(j)r^{j\theta}_{ik} + \theta(i)r^{+}_{ik}\theta(j)r^{j\theta}_{ik} \right)$$

$$+ \sum_{(s_{\theta(j)}, \tilde{h}(s_{\theta(j)})) \in LIH_2} \frac{1}{(2t+1)^2 \#\tilde{h}(s_{\theta(j)})} \sum_{\tilde{r}_{jp} \in \tilde{h}(s_{\theta(j)}); \tilde{r}_{jp} \in \tilde{h}^j(s_{\theta(j)})} \left( \theta(j)r^{-}_{jp}\theta(i)r^{i\theta}_{jp} + \theta(j)r^{+}_{jp}\theta(i)r^{i\theta}_{jp} \right)$$

(18)

where $\#\tilde{h}(s_{\theta(i)})$ and $\#\tilde{h}(s_{\theta(j)})$ denote the number of elements in $\tilde{h}(s_{\theta(i)})$ and $\tilde{h}(s_{\theta(j)})$, respectively, and the other notations as shown above.

**Example 3.8.** Let $S = \{s_1, s_2, s_3, s_4, s_5\}$ be the predefined linguistic term set. Let $LIH_1 = \{(s_1, [0.4, 0.5], [0.7, 0.8]), (s_3, [0.2, 0.3], [0.5, 0.7], [0.4, 0.6])\}$ and $LIH_2 = \{(s_2, [0.2, 0.4]), (s_3, [0.5, 0.6], [0.7, 0.9])\}$ be two LIHFSs for $S$.

Following formula (18), we have $C(LIH_1, LIH_2) = 0.828$.

**Property 3.9.** Let $LIH_1$ and $LIH_2$ be any two LIHFSs for the predefined linguistic term set $S = \{s_1, s_2, ..., s_{2t+1}\}$. The correlation defined in formula (18) satisfies:

(i) $C(LIH_1, LIH_1) = 2E(LIH_1)$ with $E(LIH_1) = \frac{1}{(2t+1)^2 \#\tilde{h}(s_{\theta(i)})} \sum_{\tilde{r}_{ik} \in \tilde{h}(s_{\theta(i)})} \left( \theta(i)^2(r^{-}_{ik})^2 + (\theta(i))^2(r^{+}_{ik})^2 \right)$;

(ii) $C(LIH_1, LIH_2) = C(LIH_2, LIH_1)$.

Proof. Following formula (18), one can easily derive the conclusions. 

3.3 Two correlation coefficients of LIHFSs

On the basis of the correlation listed in subsection 3.2, this subsection focuses on correlation coefficients of LIHFSs.

**Definition 3.10.** Let $LIH_1$ and $LIH_2$ be any two LIHFSs for the predefined linguistic term set $S = \{s_1, s_2, ..., s_{2t+1}\}$. Then, their correlation coefficients are defined as follows:

(i) The geometric mean based correlation coefficient:

$$CC_1(LIH_1, LIH_2) = \frac{C(LIH_1, LIH_2)}{\sqrt{E(LIH_1)E(LIH_2, LIH_1)} + \sqrt{E(LIH_2)E(LIH_1, LIH_2)}}$$

(19)
(ii) The maximum based correlation coefficient:

\[
CC_2(LIH_1, LIH_2) = \frac{C(LIH_1, LIH_2)}{\max \{ E(LIH_1), E(LIH_2) \} + \max \{ E(LIH_2), E(LIH_1) \}}
\]

where

\[
E(LIH_1) = \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \frac{1}{(2t+1)^2 \#h(s_{\theta(j)})} \sum_{\tilde{r}_{ip} \in h(s_{\theta(j)})} \left( (\theta(j))^2 (r_{ip}^{-})^2 + (\theta(j))^2 (r_{ip}^{+})^2 \right)
\]

\[
E(LIH_2^{LH_1}) = \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_2} \frac{1}{(2t+1)^2 \#h(s_{\theta(j)})} \sum_{\tilde{r}_{ip} \in h(s_{\theta(j)})} \left( (\theta(j))^2 (r_{ip}^{-})^2 + (\theta(j))^2 (r_{ip}^{+})^2 \right)
\]

\[
E(LIH_1^{LH_2}) = \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \frac{1}{(2t+1)^2 \#h(s_{\theta(j)})} \sum_{\tilde{r}_{ip} \in h(s_{\theta(j)})} \left( (\theta(j))^2 (r_{ip}^{-})^2 + (\theta(j))^2 (r_{ip}^{+})^2 \right)
\]

and the other notations as shown above.

Correlation coefficients defined in formulae (19) and (20) neither consider the length of the LIHFSs nor arrange the interval possible values in an increasing order.

To show the rationality of correlation coefficients listed in Definition 3.7, we consider the following several desirable properties:

**Property 3.11.** Let LIH_1 and LIH_2 be any two LIHFSs for the predefined linguistic term set \( S = \{ s_1, s_2, ..., s_{2t+1} \} \). Then, correlation coefficients defined in formulae (19) and (20) satisfy:

(i) \( CC_1(LIH_1, LIH_2) = CC_2(LIH_1, LIH_1) = 1 \);

(ii) \( CC_q(LIH_1, LIH_2) = CC_q(LIH_2, LIH_1) \), \( q = 1, 2 \);

(iii) \( 0 \leq CC_q(LIH_1, LIH_2) \leq 1 \), \( q = 1, 2 \).

**Proof.** The conditions (i) and (ii) are obvious.

For (iii): Following formula (19), one can find that \( CC_1(LIH_1, LIH_2) \geq 0 \). According to the Cauchy-Schwarz inequality

\[
(x_1y_1 + x_2y_2 + ... + x_ny_n)^2 \leq (x_1^2 + x_2^2 + ... + x_n^2)(y_1^2 + y_2^2 + ... + y_n^2)
\]

where \( x_i, y_i \in R \), \( i = 1, 2, ..., n \), we obtain

\[
\left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \frac{1}{(2t+1)^2 \#h(s_{\theta(j)})} \sum_{\tilde{r}_{ip} \in h(s_{\theta(j)})} \left( (\theta(i)r_{ip}^{-} (\theta(j) - r_{ip}^{+}) + (\theta(i)r_{ip}^{+} (\theta(j) - r_{ip}^{-}) \right) \right)^2
\]

\[
= \left( \sum_{\tilde{r}_{ip} \in h(s_{\theta(j)})} \left( (\theta(i)r_{ip}^{-} (\theta(j) - r_{ip}^{+}) + (\theta(i)r_{ip}^{+} (\theta(j) - r_{ip}^{-}) \right) \right)^2
\]

\[
+ \sum_{\tilde{r}_{ip} \in h(s_{\theta(j)})} \left( (\theta(n)r_{ip}^{-} (\theta(n) - r_{ip}^{+}) + (\theta(n)r_{ip}^{+} (\theta(n) - r_{ip}^{-}) \right) \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} \theta(n) + \theta(n)r_{ip}^{+} \theta(i) \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} \theta(n) + \theta(n)r_{ip}^{+} \theta(i) \right)^2
\]

\[
\leq \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]

\[
= \left( \sum_{(s_{\theta(j)}, h(s_{\theta(j)})) \in LIH_1} \theta(i)r_{ip}^{-} + \theta(n)r_{ip}^{+} \right)^2
\]
Similarly, we have
\[
\sum_{(s_{t(j)}, h(s_{t(j)}))\in LIH_2} \frac{1}{(2t+1)^2 \#(s_{t(j)})} \sum_{r_i^k \in h(s_{t(j)}); r_i^p \in h_j(s_{t(j)})} \frac{1}{(2t+1)^2 \#(s_{t(j)})} \sum_{r_i^k \in h(s_{t(j)}); r_i^p \in h_j(s_{t(j)})} (\theta(j)r_i^k \theta(i)r_i^p) \leq \sqrt{E(LIH_1)E(LIH_2^{LIH_2})}
\]
(22)

On the basis of formulae (21) and (22), we obtain
\[
C(LIH_1, LIH_2) \leq \sqrt{E(LIH_1)E(LIH_2^{LIH_1})} + \sqrt{E(LIH_2)E(LIH_1^{LIH_2})}
\]
by which, \( CC_1(LIH_1, LIH_2) \leq 1 \).

Similar to the proof of formula (19), one can derive the conclusions for formula (20).

**Property 3.12.** Let \( LIH_1 \) and \( LIH_2 \) be any two LIHFSs for the predefined linguistic term set \( S = \{s_1, s_2, \ldots, s_{2t+1}\} \). Then, \( CC_1(LIH_1, LIH_2) \geq CC_2(LIH_1, LIH_2) \).

Formula (19) is the ratio between \( C(LIH_1, LIH_2) \) and \( \left( \sqrt{E(LIH_1)E(LIH_2^{LIH_1})} + \sqrt{E(LIH_2)E(LIH_1^{LIH_2})} \right) \), and formula (20) is the ratio between \( C(LIH_1, LIH_2) \) and \( \max \{E(LIH_1), E(LIH_2^{LIH_1})\} + \max \{E(LIH_2), E(LIH_1^{LIH_2})\} \).

It is noteworthy that the optimistic DMs can apply the geometric mean based correlation coefficient, while the pessimistic DMs may employ the maximum based correlation coefficient.

**Example 3.13.** Let \( LIH_1 \) and \( LIH_2 \) be two LIHFSs for \( S = \{s_1, s_2, s_3, s_4, s_5\} \), where
\[
LIH_1 = \{s_1, [0.1, 0.3], [0.5, 0.7], s_3, [0.3, 0.4], [0.6, 0.8]\}
\]
\[
LIH_2 = \{s_1, [0.1, 0.2], [0.5, 0.6], [0.7, 0.9], s_4, [0.4, 0.6]\}
\]
Following formula (19), the geometric mean based correlation coefficient of \( LIH_1 \) and \( LIH_2 \) is \( CC_1(LIH_1, LIH_2) = 0.811 \); on the basis of formula (20), the maximum based correlation coefficient of LIHFSs \( LIH_1 \) and \( LIH_2 \) is \( CC_2(LIH_1, LIH_2) = 0.720 \).

### 3.4 Two shapley weighted correlation coefficients of LIHFSs

As many researchers noted, interdependences between the weights of elements in a set may exist [28, 39]. To address this issue, the Shapley function with respect to fuzzy measures is an ideal tool that has been widely used in decision making. This subsection defines two Shapley weighted correlation coefficients of LIHFSs.

**Definition 3.14.** Let \( LIH^1 = \{LIH_1^1, LIH_1^2, \ldots, LIH_n^1\} \) and \( LIH^2 = \{LIH_1^2, LIH_2^2, \ldots, LIH_n^2\} \) be two collections of LIHFSs for the predefined linguistic term set \( S = \{s_1, s_2, \ldots, s_{2t+1}\} \). The Shapley weighted correlation coefficients are defined as follows:

(i) The geometric mean based Shapley weighted correlation coefficient:
\[
CC_1^\varphi(LIH^1, LIH^2) = \sum_{l=1}^n \varphi_l(\mu, N)CC_1(LIH_1^l, LIH_2^l)
\]

(ii) The maximum based Shapley weighted correlation coefficient:
\[
CC_2^\varphi(LIH^1, LIH^2) = \sum_{l=1}^n \varphi_l(\mu, N)CC_2(LIH_1^l, LIH_2^l)
\]
(ii) The maximum based Shapley weighted correlation coefficient:

\[
CC_\phi^\phi(LIH^1, LIH^2) = \sum_{l=1}^{n} \varphi_l(\mu, N)CC_2(LIH^1_l, LIH^2_l)
\]

where \(\varphi_l(\mu, N)\) is the Shapley value of the index \(l\) with respect to the fuzzy measure on the set \(N = \{1, 2, ..., n\}, l = 1, 2, ..., n\).

Note that the Shapley weighted correlation coefficients offered in Definition 3.9 have the similar properties for linguistic interval hesitant fuzzy correlation coefficients listed in Definition 3.7.

**Property 3.15.** Let \(LIH^1 = \{LIH^1_1, LIH^1_2, ..., LIH^1_n\}\) and \(LIH^2 = \{LIH^2_1, LIH^2_2, ..., LIH^2_n\}\) be two collections of LIHFSs for the predefined linguistic term set \(S = \{s_1, s_2, ..., s_{2t+1}\}\). The Shapley weighted correlation coefficients defined in formulae (23) and (24) satisfy:

(i) \(CC_\phi^\phi(LIH^1, LIH^1) = CC_\phi^\phi(LIH^2, LIH^1) = 1\);

(ii) \(CC_\phi^\phi(LIH^1, LIH^2) = CC_\phi^\phi(LIH^2, LIH^1), q = 1, 2\);

(iii) \(0 \leq CC_\phi^\phi(LIH^1, LIH^2) \leq 1, q = 1, 2\).

Subsection 3.3 offers two correlation coefficients of LIHFSs based on the assumption that the weights of elements are independent and have the same importance. On the other hand, the Shapley weighted correlation coefficients (23) and (24) define the interactive weights of elements in a set. When there are no interactions between the weights of elements, the Shapley weighted correlation coefficients degenerate to the associated weighted correlation coefficients as follows:

(i) The geometric mean based weighted correlation coefficient:

\[
CC_\omega^\omega(LIH^1, LIH^2) = \sum_{l=1}^{n} \omega_l CC_1(LIH^1_l, LIH^2_l)
\]

(ii) The maximum based weighted correlation coefficient:

\[
CC_\mu^\mu(LIH^1, LIH^2) = \sum_{l=1}^{n} \omega_l CC_2(LIH^1_l, LIH^2_l)
\]

where \(\omega_l\) is the weight of the index \(l, l = 1, 2, ..., n\).

Similar to the property above mentioned, we have the following properties for the (Shapley) weighted correlation coefficients.

**Property 3.16.** Let \(LIH^1 = \{LIH^1_1, LIH^1_2, ..., LIH^1_n\}\) and \(LIH^2 = \{LIH^2_1, LIH^2_2, ..., LIH^2_n\}\) be two collections of LIHFSs for the predefined linguistic term set \(S = \{s_1, s_2, ..., s_{2t+1}\}\). Then,

(i) \(CC_\omega^\omega(LIH^1, LIH^2) \geq CC_\omega^\omega(LIH^1, LIH^2)\);

(ii) \(CC_\mu^\mu(LIH^1, LIH^2) \geq CC_\mu^\mu(LIH^1, LIH^2)\).

Similar to the analysis of correlation coefficients defined in Subsection 3.3, the pessimistic DMs can choose the geometric mean based (Shapley) weighted correlation coefficient, while the optimistic DMs prefer to adopt the maximum based (Shapley) weighted correlation coefficient.

# 4 An approach to pattern recognition

Pattern recognition originated from 1920s is the primary implementation approach, which aims to identify sample based on mathematical methods. This section applies the defined correlation coefficients of LIHFSs to present an approach to pattern recognition with linguistic interval hesitant fuzzy information.

Considering a pattern recognition problem, let \(A = \{a_1, a_2, ..., a_n\}\) be the set of patterns, and let \(C = \{c_1, c_2, ..., c_n\}\) be the set of features. A LIHFS \(LIH_{ij}\) is the evaluation of the pattern \(a_i\) with respect to the feature \(c_j, \ i = 1, 2, ..., m; \ j = 1, 2, ..., n\). Let \(LIH_i = \{LIH_{i1}, LIH_{i2}, ..., LIH_{im}\}\), \(i = 1, 2, ..., m\), be the sets of LIHFSs for patterns, and let \(LIH = \{LIH_1, LIH_2, ..., LIH_n\}\) be the set of LIHFSs for the sample \(p\) with respect to the feature set \(C\).

When the weight information is exactly known, we can apply correlation coefficients of LIHFSs offered in Section 3 to discriminate the sample \(p\) belonging to which type of patterns. Otherwise, we first need to determine the weight vector on the feature set. Since all patterns are non-inferior, and the weight vector makes the comprehensive values the bigger the better, the following programming model for the optimal fuzzy measure \(\mu\) on \(C\) is established:

\[
\min \sum_{j=1}^{m} \sum_{i=1}^{n} \varphi_{c_j}(\mu, C)d(LIH_{ij}, LIH_j)
\]
Example 4.1. Let the algorithm for pattern recognition with linguistic interval hesitant fuzzy information be:

\[ \begin{align*}
\text{optimal additive weight vector on the feature set } C \\
\text{on the basis of correlation coefficients obtained in Step 3, the sample } \text{choose the used correlation coefficients following their risk preferences and decision-making problems.}
\end{align*} \]

When there is no interaction between the weights of features, models (27) and (28) reduce to programming models for the optimal additive weight vector on the feature set \( C \).

Based on the defined correlation coefficients of LIHFSs and the built models for the optimal weight vector, the following algorithm for pattern recognition with linguistic interval hesitant fuzzy information is offered:

**Step 1:** Following model (28), we get:

\[ \begin{align*}
\text{Step 1: Following model (28), we get:} \\
\sum_{j=1}^{m} d(LIH_{ij}, LIH_{ij}) \mu(c_j) + \frac{1}{2} \sum_{j=1}^{m} d(LIH_{ij}, LIH_{ij}) (\mu(c_j, c_j) - \mu(c_i)) \\
\text{s.t.} \\
\sum_{c_j \subseteq S} (\mu(c_j, c_i) - \mu(c_i)) \geq (s - 2) \mu(c_j), \quad \forall c_j, \in S \subseteq C, s \geq 2 \\
\sum_{c_j \subseteq C} \mu(c_j, c_i) - (c - 2) \sum_{c_j \subseteq C} \mu(c_j) = 1 \\
\mu(c_j) \in W_j, \mu(c_j) \geq 0, \quad j = 1, 2, ..., n
\end{align*} \]

**Step 4:** End.

**Step 3:** On the basis of CC\(_2\)'s LIH, \( i = 1, 2, 3 \), we conclude that the patient \( p \) had typhoid. However, the patient \( p \) had viral fever based on CC\(_2\)'s LIH, \( i = 1, 2, 3 \).

**Step 4:** End.

The result shows that different optimal patterns may be derived for different correlation coefficients. Thus, the DMs need to choose the used correlation coefficients following their risk preferences and decision-making problems.
5 An approach to decision making with LIHFSs

This section considers decision making with linguistic interval hesitant fuzzy information. Without loss of generality, let $S = \{s_1, s_2, ..., s_{2^t+1}\}$ be the predefined linguistic term set, let $A = \{a_1, a_2, ..., a_m\}$ be the set of attributes, and let $C = \{c_1, c_2, ..., c_n\}$ be the set of attributes. Suppose that $LIH_{ij}$ is the LIHFS of the alternative $a_i$ for the attribute $c_j$, $i = 1, 2, ..., m; j = 1, 2, ..., n$. By $LIH = (LIH_{ij})_{m \times n}$, we denote linguistic interval hesitant fuzzy decision matrix.

5.1 Models to determine the optimal weight vector

As the analysis for pattern recognition, when the weight information is incompletely known, we first need to determine the weight vector on the attribute set.

Let $LIH_j$ be the $j$th column of the linguistic interval hesitant fuzzy decision matrix $LIH$, and let

$$LIH_j^+ = \bigcup_{i=1}^{m} LIH_{ij} = \{(s_{\max_{i=1}^{2} \theta(i)}, \max_{i=1}^{m}\{r_{ij}^+\}, \max_{i=1}^{m}\{r_{ij}^-\})|\bar{r}_{ij} = [r_{ij}^-, r_{ij}^+] \in LIH_{ij}, i = 1, 2, ..., m\}$$

$$LIH_j^- = \bigcup_{i=1}^{m} LIH_{ij} = \{(s_{\min_{i=1}^{2} \theta(i)}, \min_{i=1}^{m}\{r_{ij}^+\}, \min_{i=1}^{m}\{r_{ij}^-\})|\bar{r}_{ij} = [r_{ij}^-, r_{ij}^+] \in LIH_{ij}, i = 1, 2, ..., m\}$$

for each $j = 1, 2, ..., n$ and $S_{\theta(i)} \subseteq S$.

Let $LIH^+ = \{LIH_j^+, LIH_{j+1}^+, ..., LIH_n^+\}$ and $LIH^- = \{LIH_j^-, LIH_{j+1}^-, ..., LIH_n^-\}$.

When the weight information on the attribute set is incompletely known, we establish the following programming model for obtaining the optimal fuzzy measure $\mu$ on $C$:

$$\min \sum_{j=1}^{n} \sum_{i=1}^{m} \varphi_{c_j}(\mu, C) \frac{d(LIH_{ij}, LIH_j^+)}{d(LIH_{ij}, LIH_j^+) + d(LIH_{ij}, LIH_j^-)}$$

s.t. \begin{align*}
\mu(C) & = 1 \\
\mu(S) & \leq \mu(T), \quad \forall S, T \subseteq C \quad s.t. S \subseteq T \\
\mu(c_j) & \in W_j, \mu(c_j) \geq 0, \quad j = 1, 2, ..., n
\end{align*}

(29)

where $\varphi_{c_j}(\mu, C)$ is the Shapley value of the attribute $c_j$ with respect to the fuzzy measure $\mu$ on $C$, $d(LIH_{ij}, LIH_j^+)$ is the distance measure between $LIH_{ij}$ and $LIH_j^+$, $d(LIH_{ij}, LIH_j^-)$ is the distance measure between $LIH_{ij}$ and $LIH_j^-$, and $W_j$ is the known weight information.

Similarly, we derive the following programming model for ascertaining the optimal 2-additive measure $\mu$ on $C$:

$$\min \frac{3-n}{2} \sum_{j=1}^{n} \sum_{i=1}^{m} \frac{d(LIH_{ij}, LIH_j^+)}{d(LIH_{ij}, LIH_j^+) + d(LIH_{ij}, LIH_j^-)} \mu(c_j)$$

$$+ \frac{1}{2} \sum_{j=1}^{n} \sum_{i=1}^{m} \frac{d(LIH_{ij}, LIH_j^+)}{d(LIH_{ij}, LIH_j^+) + d(LIH_{ij}, LIH_j^-)} (\mu(c_j, c_i) - \mu(c_j))$$

s.t. \begin{align*}
\sum_{c_j \subseteq C} (\mu(c_j, c_i) - \mu(c_j)) & \geq (s-2)\mu(c_j), \quad \forall c_j \in S \subseteq C, s \geq 2 \\
\sum_{c_j \subseteq C} \mu(c_j, c_i) - (c-2) & \sum_{c_j \subseteq C} \mu(c_j) = 1 \\
\mu(c_j) & \in W_j, \mu(c_j) \geq 0, \quad j = 1, 2, ..., n
\end{align*}

(30)

where the notations as shown in model (29).

When there are no interactions between the weights of attributes, models (29) and (30) degenerate to models for the optimal additive measure on the attribute set $C$.

5.2 An algorithm

Following the above discussions, this subsection introduces the following algorithm for multi-attribute decision making with linguistic interval hesitant fuzzy information.

Step 1: Let $LIH = (LIH_{ij})_{m \times n}$ be the linguistic interval hesitant fuzzy decision matrix. When all attributes are benefit, the attribute values needn’t transformation. Otherwise, we need to transform $LIH = (LIH_{ij})_{m \times n}$ into $LIH' = (LIH'_{ij})_{m \times n}$, where $LIH'_{ij} = \{\begin{array}{ll}LIH_{ij} & c_j \text{ is a benefit attribute} \\
 LIH_{ij} & c_j \text{ is a cost attribute} \end{array}$ for all $i = 1, 2, ..., m; j = 1, 2, ..., n$. 
Step 2: When the weight information is exactly known, go to step 4. Otherwise, model (30) is used to determine the optimal fuzzy measure \( \mu \) on the attribute set \( C \);

Step 3: Formulae (23) or (24) and (25) or (26) are adopted to calculate the (Shapley) weighted correlation coefficients between \( LIH'_i \) and \( LIH^+ \) as well as \( LIH'_i \) and \( LIH^- \), \( i = 1, 2, ..., m \);

Step 4: The following formulae are applied to calculate the ranking values:

\[
CC^p_{r_i} = \frac{CC^p_{\mu}(LIH'_i, LIH^+)}{CC^p_{\mu}(LIH'_i, LIH^+) + CC^p_{\mu}(LIH'_i, LIH^-)} \quad p = 1, 2
\]

(31)

\[
CC^p_{r_i} = \frac{CC^p_{\phi}(LIH'_i, LIH^+)}{CC^p_{\phi}(LIH'_i, LIH^+) + CC^p_{\phi}(LIH'_i, LIH^-)} \quad p = 1, 2
\]

(32)

for all \( i = 1, 2, ..., m \), where \( LIH'_i \) denotes the \( i \)th row of \( LIH' \);

Step 5: Following the ranking values of \( CC^p_{r_i} \) or \( CC^p_{r_i} \), \( i = 1, 2, ..., m ; p = 1, 2 \) the best choice is obtained;

Step 6: End.

**Example 5.1.** Considering a tunnel bidding, four constructors \( A = \{a_1, a_2, a_3, a_4\} \) submit their tenders for building a tunnel. To evaluate these constructors, the following four attributes are considered \( c_1 \): credit (Bidder's credit is an important index for bidding evaluation, the higher the bidder's credit rate is, the higher the winning probability will be); \( c_2 \): tender offer (The tender offer is the total price of a contract that is calculated and determined by contractor, the traditional approach adopts the principle of minimum tender offer); \( c_3 \): the limitation of project time (The limitation of project time is one of the important indexes to measure construction enterprises. The length of project time directly affects the economic benefits of construction enterprises. Under the premise of ensuring quality, the shorter the time is, the higher the economic benefits will be); \( c_4 \): the scale of company (Generally speaking, companies with large scale, good equipment, high-quality talents and good management measures have a certain influence on winning). To avoid influencing each other, the DMs are required to provide their preferences anonymously. Because of the limited expertise and the complexity of considering attributes, it is difficult or impossible to require the DMs to offer quantitative judgments. To address this issue, the DMs are allowed to apply linguistic variables. Meanwhile, the DMs may also want to express their quantitative judgments for the given linguistic variables. Furthermore, the DMs may hesitate on several possible values. To cope with these situations, LIHFSs are good tools. Let \( S = \{s_1: \text{poor}, s_2: \text{slightly poor}, s_3: \text{fair}, s_4: \text{slightly good}, s_5: \text{good}\} \) be the predefined linguistic term set. Suppose that the linguistic interval hesitant fuzzy decision matrix \( LIH = (LIH_{i,j})_{4 \times 4} \) is offered in Table 1.

Table 1: Linguistic interval hesitant fuzzy decision matrix \( LIH \)

To select the best constructor, the following steps are needed:

Step 1: Because \( c_2 \) and \( c_4 \) are cost attributes, we need to transform the linguistic interval hesitant fuzzy decision matrix \( LIH \) into the normalized linguistic interval hesitant fuzzy decision matrix \( LIH' \) as shown in Table 2:

Step 2: Suppose that weight vector on the attribute set is defined as \( W_c = (0.15, 0.2, 0.3, 0.4, 0.25, 0.3, 0.25, 0.25) \). According to model (30), we obtain:

\[
\mu(c_1) = 0.2, \mu(c_2) = 0.3, \mu(c_3) = 0.25, \mu(c_4) = 0.2, \mu(c_1, c_2) = 0.55, \mu(c_1, c_3) = 0.45, \mu(c_2, c_3) = 0.55, \mu(c_1, c_4) = 0.4, \mu(c_2, c_4) = 0.5, \mu(c_3, c_4) = 0.45.
\]

Furthermore, the Shapley values are

\[
\varphi_{c_1}(\mu, C) = 0.22, \varphi_{c_2}(\mu, C) = 0.33, \varphi_{c_3}(\mu, C) = 0.25, \varphi_{c_4}(\mu, C) = 0.2.
\]

Step 3: The geometric mean based Shapley weighted correlation coefficients are

\[
CC^p_{\phi}(LIH^1_{i,j}, LIH^+) = 0.963, CC^p_{\phi}(LIH^2_{i,j}, LIH^+) = 0.957, CC^p_{\phi}(LIH^3_{i,j}, LIH^+) = 0.952, CC^p_{\phi}(LIH^4_{i,j}, LIH^+) = 0.978, CC^p_{\phi}(LIH^1_{i,j}, LIH^-) = 0.822, CC^p_{\phi}(LIH^2_{i,j}, LIH^-)
\]
by which we drive the same ranking order as follows:

\[
\begin{align*}
&\{s_2, 0.1, 0.3\}, \quad \{s_2, 0.3, 0.7\}, \quad \{s_2, 0.3, 0.7\}, \quad \{s_2, 0.3, 0.7\}, \\
&a_1 \quad \{s_4, 0.2, 0.3\} \quad \{s_4, 0.2, 0.3\} \quad \{s_4, 0.2, 0.3\} \quad \{s_4, 0.2, 0.3\} \\
&\{s_5, 0.4, 0.6\} \quad \{s_5, 0.4, 0.6\} \quad \{s_5, 0.4, 0.6\} \quad \{s_5, 0.4, 0.6\} \\
&a_2 \quad \{s_1, 0.5, 0.8\} \quad \{s_2, 0.8, 0.9\} \quad \{s_2, 0.8, 0.9\} \quad \{s_2, 0.8, 0.9\} \\
&\{s_2, 0.5, 0.7\} \quad \{s_2, 0.6, 0.8\} \quad \{s_4, 0.2, 0.4\} \quad \{s_4, 0.2, 0.4\} \\
&a_3 \quad \{s_4, 0.2, 0.3\} \quad \{s_4, 0.2, 0.3\} \quad \{s_4, 0.2, 0.3\} \quad \{s_4, 0.2, 0.3\} \\
&\{s_5, 0.3, 0.5\} \quad \{s_5, 0.3, 0.5\} \quad \{s_5, 0.3, 0.5\} \quad \{s_5, 0.3, 0.5\} \\
&\{0.4, 0.6\} \quad \{0.1, 0.2\} \quad \{0.1, 0.2\} \quad \{0.1, 0.2\} \\
&a_4 \quad \{0.8, 0.9\} \quad \{0.8, 0.9\} \quad \{0.8, 0.9\} \quad \{0.8, 0.9\} \\
\end{align*}
\]

Table 2: Normalized linguistic interval hesitant fuzzy decision matrix \(LIH'\)

\[
= 0.889, \quad CC_1^{CI}(LIH_3, LIH^-) = 0.842, \quad CC_1^{CI}(LIH'_3, LIH^-) = 0.979.
\]

and the maximum based Shapley weighted correlation coefficients are

\[
CC_1^{CI}(LIH_1, LIH^-) = 0.554, \quad CC_1^{CI}(LIH'_2, LIH^-) = 0.461, \quad CC_1^{CI}(LIH'_3, LIH^-) = 0.615, \quad CC_1^{CI}(LIH'_4, LIH^-) = 0.244, \quad CC_1^{CI}(LIH'_1, LIH^-) = 0.228, \quad CC_1^{CI}(LIH'_2, LIH^-) = 0.210, \quad CC_1^{CI}(LIH'_3, LIH^-) = 0.221, \quad CC_1^{CI}(LIH'_4, LIH^-) = 0.611.
\]

Step 4: Using formulae (31) and (32), the following ranking values are derived: \(CC_1^{CI} = 0.540, CC_2^{CI} = 0.518, CC_3^{CI} = 0.531, CC_4^{CI} = 0.500, CC_2^{CI} = 0.708, CC_3^{CI} = 0.686, CC_4^{CI} = 0.736, CC_4^{CI} = 0.285.\)

Step 5: Following the values of \(CC_1^{CI}, i = 1, 2, 3, 4, \) the constructor \(a_1\) is the best choice. On the basis of the values of \(CC_2^{CI}, \)
\(i = 1, 2, 3, 4, \) the constructor \(a_3\) is the best choice.

Step 6: End.

In this example, when we assume that there is no interaction between the weights of attributes, the ranking values are obtained as follows:

\[
r_1^{CC_1} = 0.540, \quad r_2^{CC_1} = 0.518, \quad r_3^{CC_1} = 0.541, \quad r_4^{CC_1} = 0.500, \quad r_1^{CC_2} = 0.717, \quad r_2^{CC_2} = 0.682, \quad r_3^{CC_2} = 0.745, \quad r_4^{CC_2} = 0.276,
\]

by which we drive the same ranking order \(r_3^{CC_1} > r_1^{CC_1} > r_2^{CC_1} > r_4^{CC_1}, \quad p = 1, 2, \) namely, the constructor \(a_3\) is the best choice.

5.3 Comparison analysis

In Example 5.1, when Meng et al.'s method [3] is applied, the final ranking values are obtained as follows:

(i) The ranking values obtained from the generalized linguistic interval hesitant fuzzy hybrid weighted averaging (GLIHFHWA)

\[
\begin{align*}
&\tilde{E}(LIH_1) = [1.1, 1.85], \quad \tilde{E}(LIH_2) = [1.42, 1.95], \quad \tilde{E}(LIH_3) = [2.93, 4.03], \quad \tilde{E}(LIH_4) = [0.61, 0.83]; \\
&(ii) \quad \text{The ranking values obtained from the generalized linguistic interval hesitant fuzzy hybrid 2-additive Shapley averaging (GLIHFH2SA)}
\end{align*}
\]

\[
\begin{align*}
&\tilde{E}(LIH_1) = [1.09, 1.92], \quad \tilde{E}(LIH_2) = [1.5, 1.88], \quad \tilde{E}(LIH_3) = [1.43, 1.99], \quad \tilde{E}(LIH_4) = [0.56, 0.79], \quad \text{where } \lambda = 2.
\end{align*}
\]

One can see that the same ranking order \(LIH_3 \succ LIH_2 \succ LIH_1 \succ LIH_4\) is obtained, namely, the constructor \(a_3\) is the best choice.

For simplicity, ranking orders with respect to the different methods are listed in Table 3.

Table 3 shows that different methods might lead to different ranking orders and different optimal choices. When the DMs make decisions, they are required to choose decision-making method according to the actual requirement. Generally speaking, we suggest the DMs to apply the Shapley weighted correlation coefficients because they can deal with the interactive characteristics between elements in a set and seem to be simpler than Meng et al.'s method [3] in some aspects.

6 Conclusions

LIHFSs are efficient tools in dealing with qualitative and quantitative vague information that appears in the engineering and scientific applications. On the other hand, correlation coefficient is one of the widely used techniques in decision-making theory. This paper took the advantages of them and presented two correlation coefficients of LIHFSs by using the defined distance measure. Meanwhile, two linguistic interval hesitant fuzzy Shapley weighted correlation coefficients are defined to address the situation where the weights of elements in a set are interactive. It's worth noting that the Shapley weighted correlation coefficient can be seen as an extension of correlation coefficients. Considering the situation where the weight information is incompletely known, models for optimal 2-additive measures on the feature set and on the attribute set are constructed. Furthermore, a method to pattern recognition and decision making under linguistic interval hesitant fuzzy environment with incomplete weight information is developed, respectively. Meanwhile, associated practical examples are offered to show the concrete applications of the developed theoretical results and a comparison analysis is offered.

It is noteworthy that new results extend the application of LIHFSs. In the future, we will continue to research correlation coefficients of other types of fuzzy sets, such as hesitant linguistic intuitionistic fuzzy sets (HLIFSs) [14], linguistic hesitant fuzzy
